

Refraction and Images Formed by Refraction

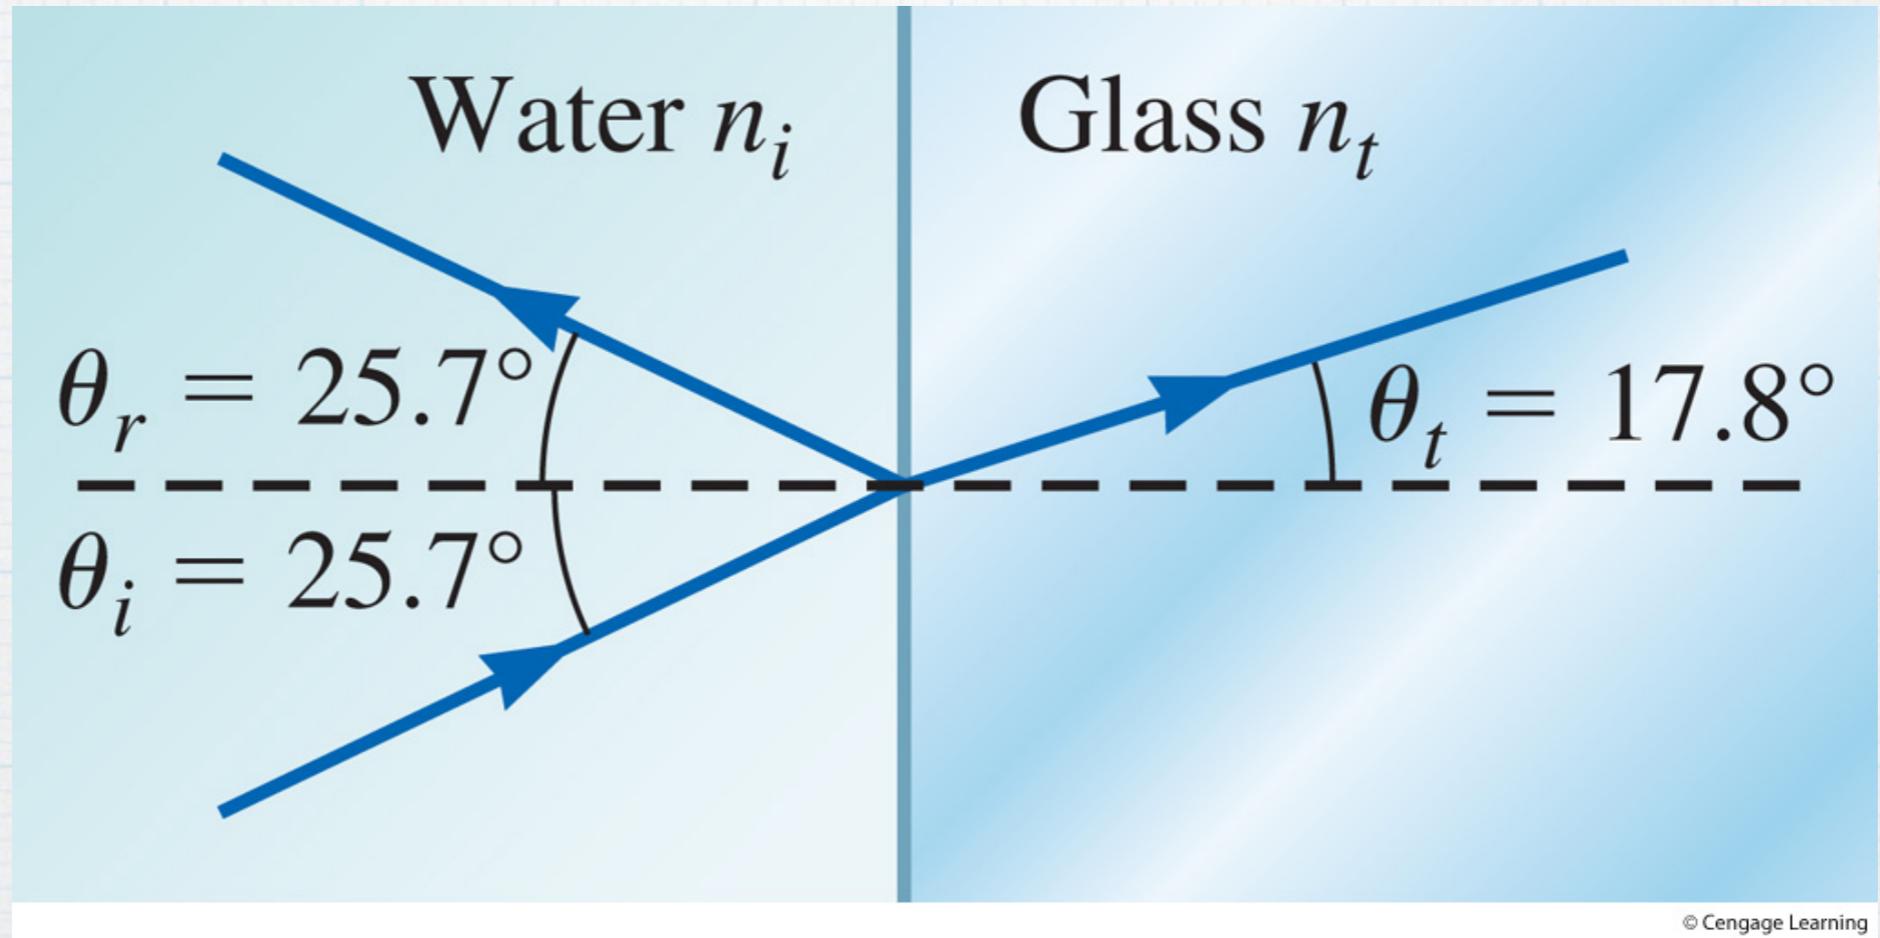

$$n_i \sin(\theta_i) = n_t \sin(\theta_t)$$

$$n = \frac{c}{v}$$

Light is refracted when
it changes media
The refracted
component bends
towards the normal
when
 $n_t > n_i$

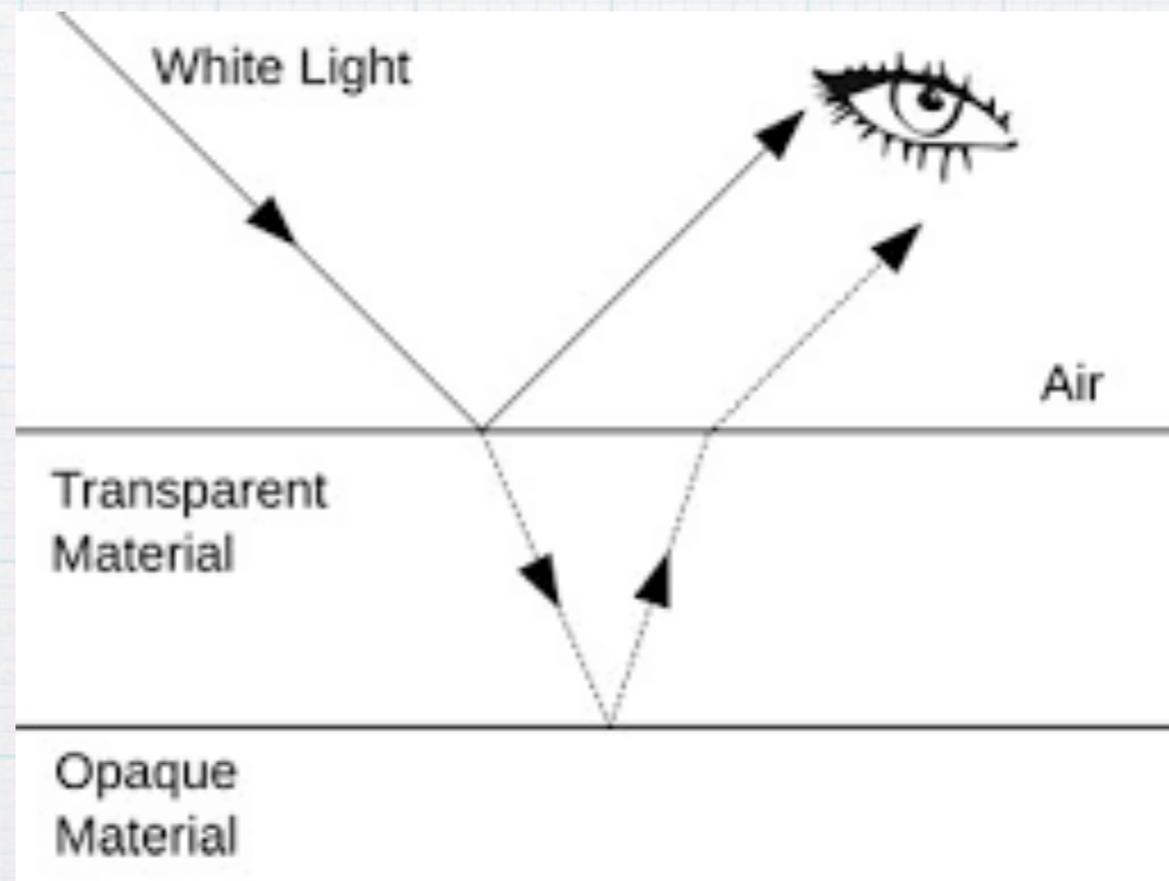

Water

$$n_{\text{water}} = 1.33$$

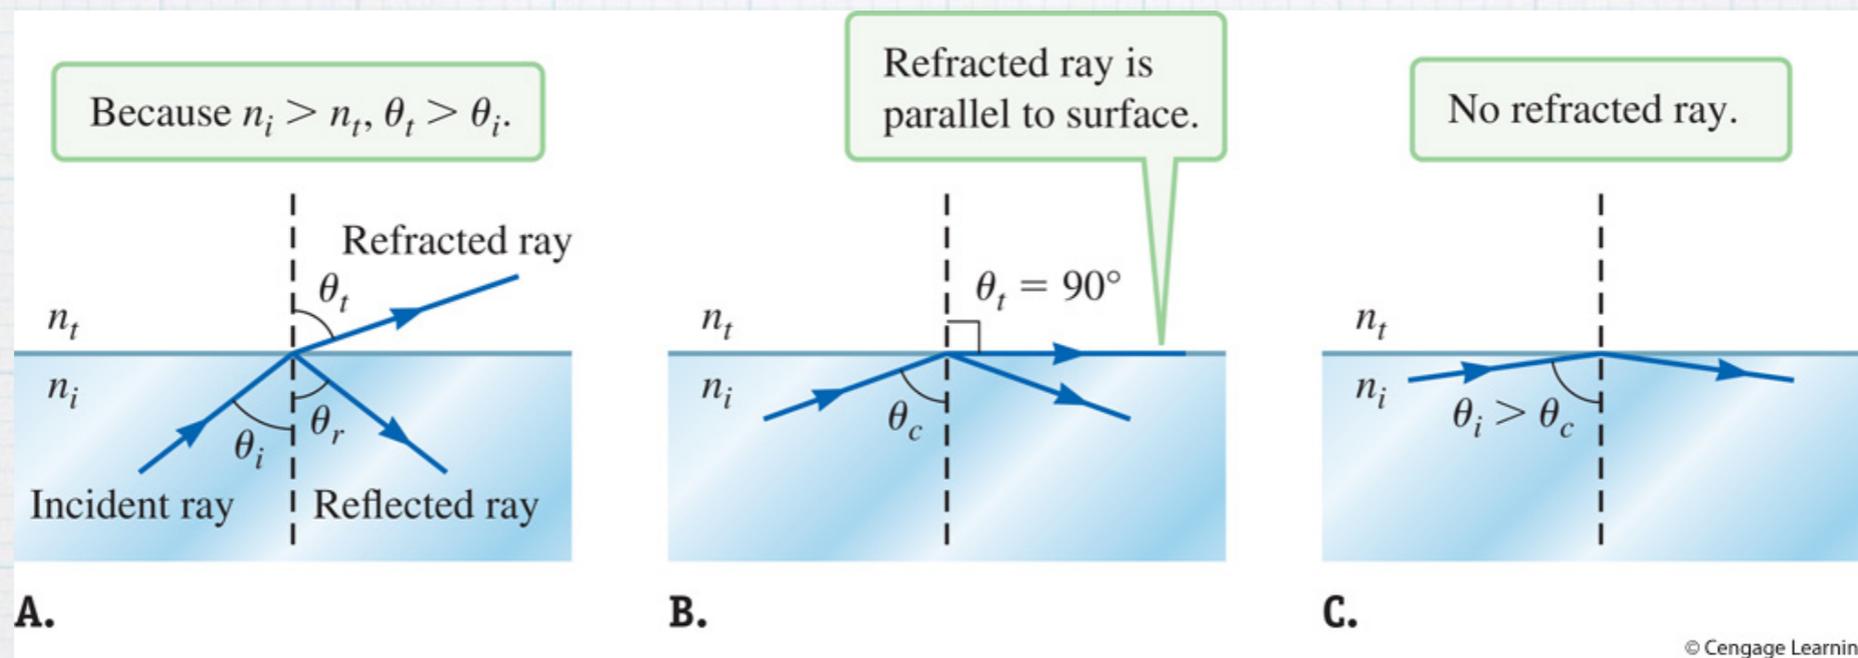

$$n_{\text{glass}} = 1.89$$

Fill in the angles

Total Internal Reflection

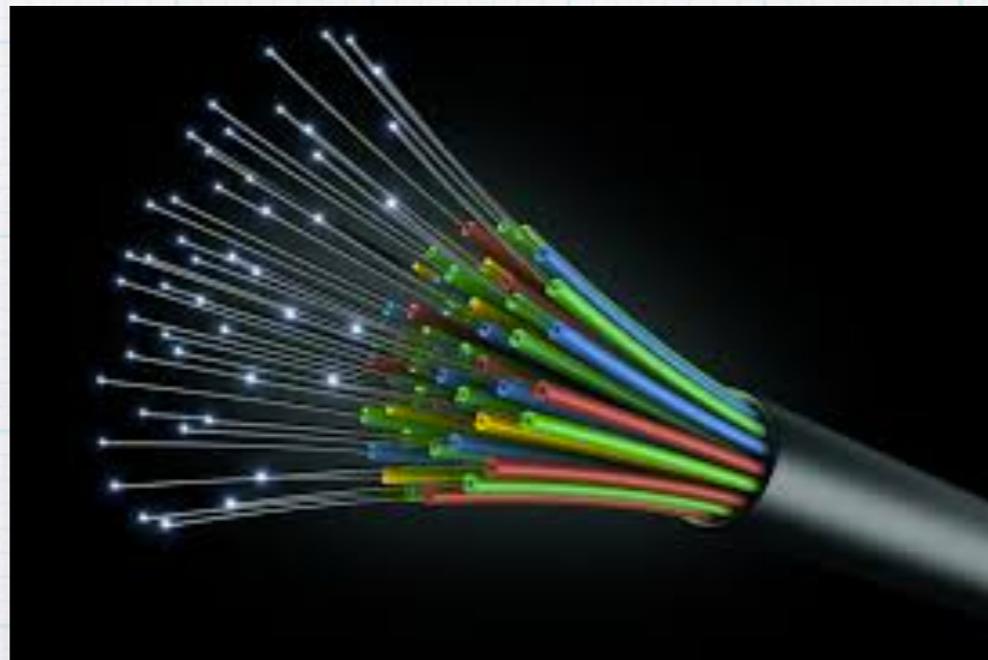

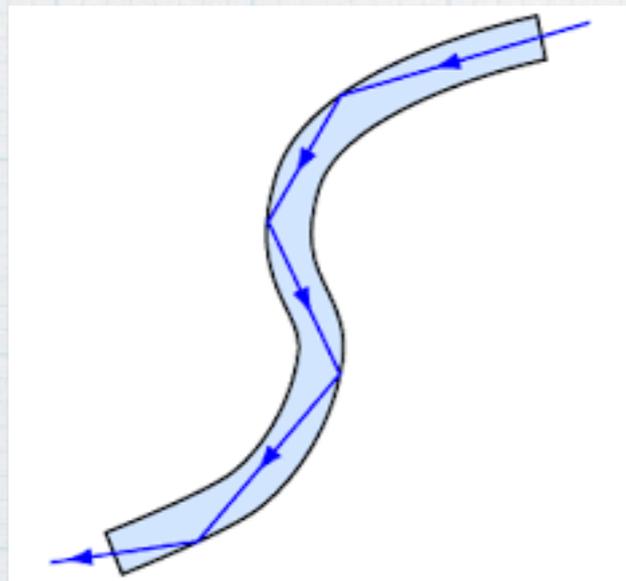

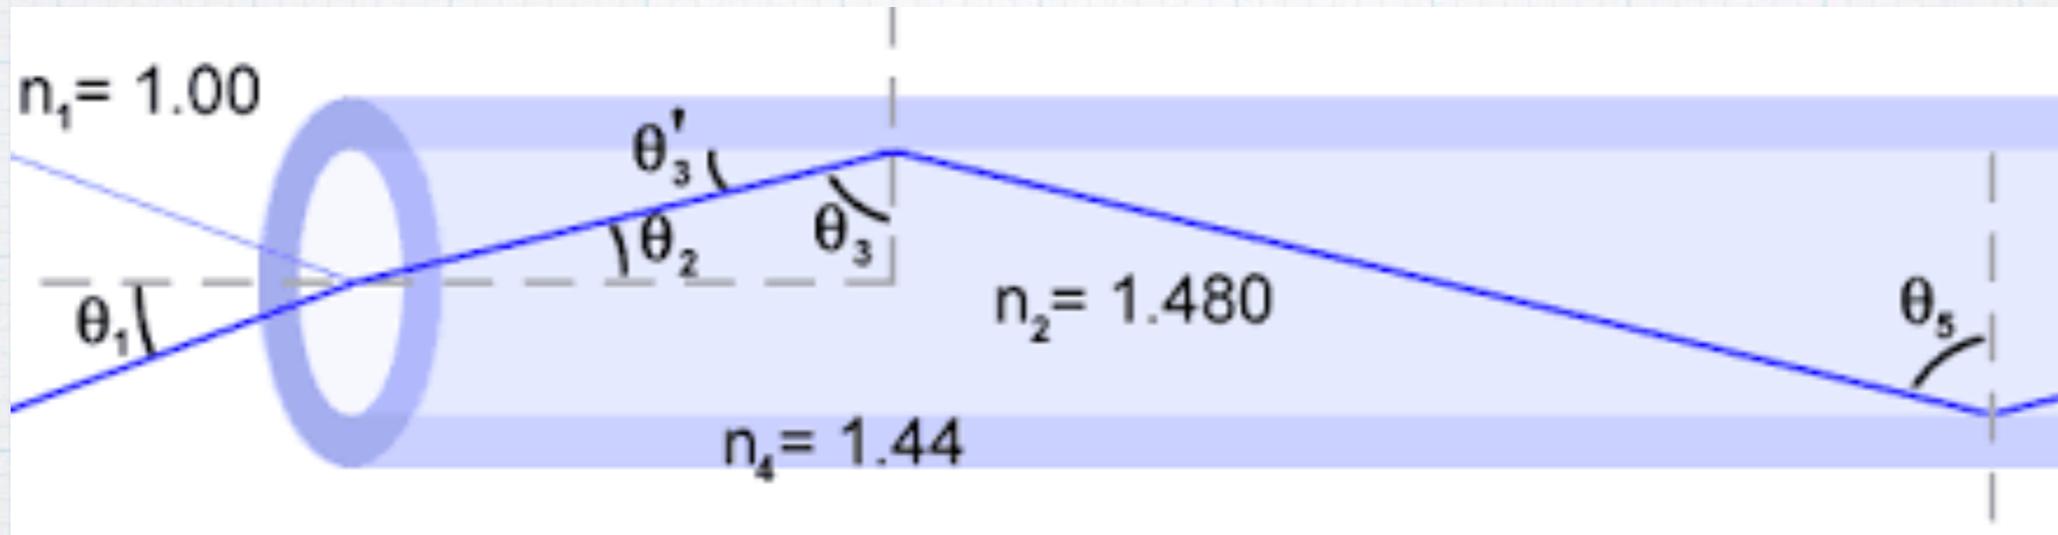

Or, how you get information through fiber optics

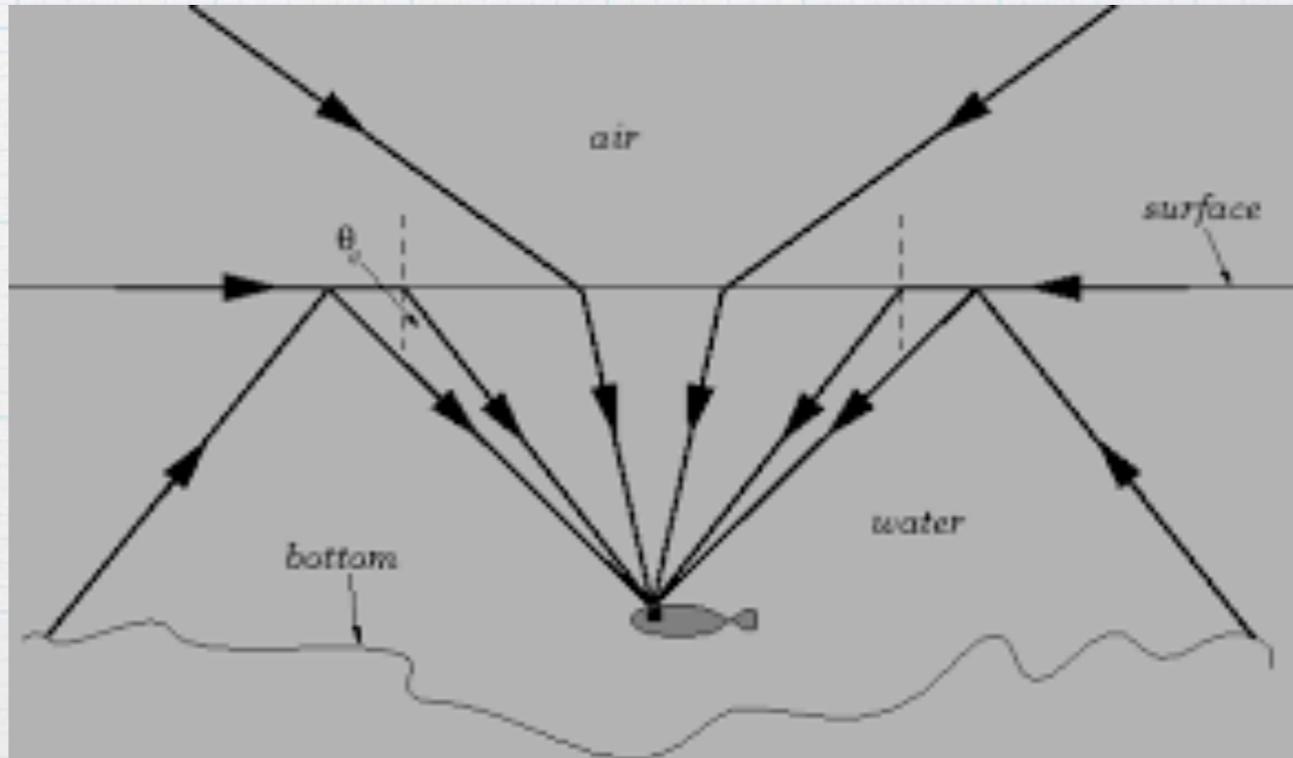

Only a possibility when $n_t < n_i$

$$\sin(\theta_c) = \frac{n_t}{n_i} \quad \text{Show}$$

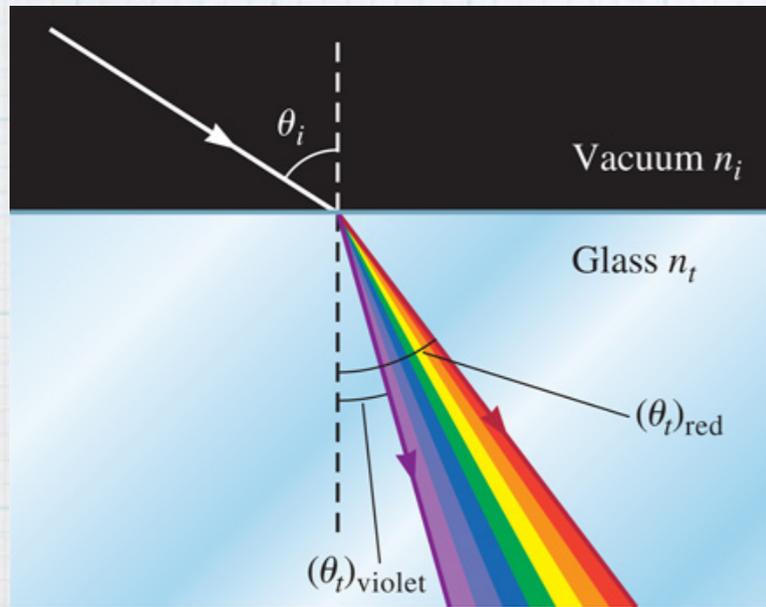

Fiber Optics

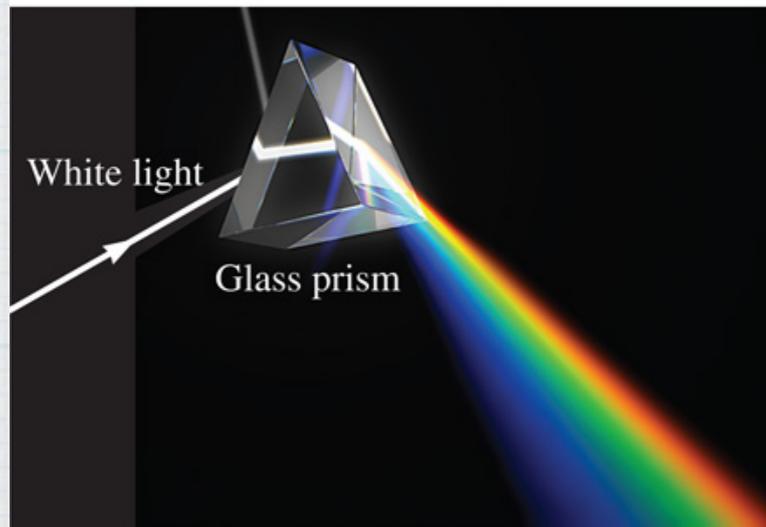

Dispersion

Or, the index of refraction is really wavelength dependent

This is how Rainbows are Formed

A. Double rainbow

B. Lower rainbow

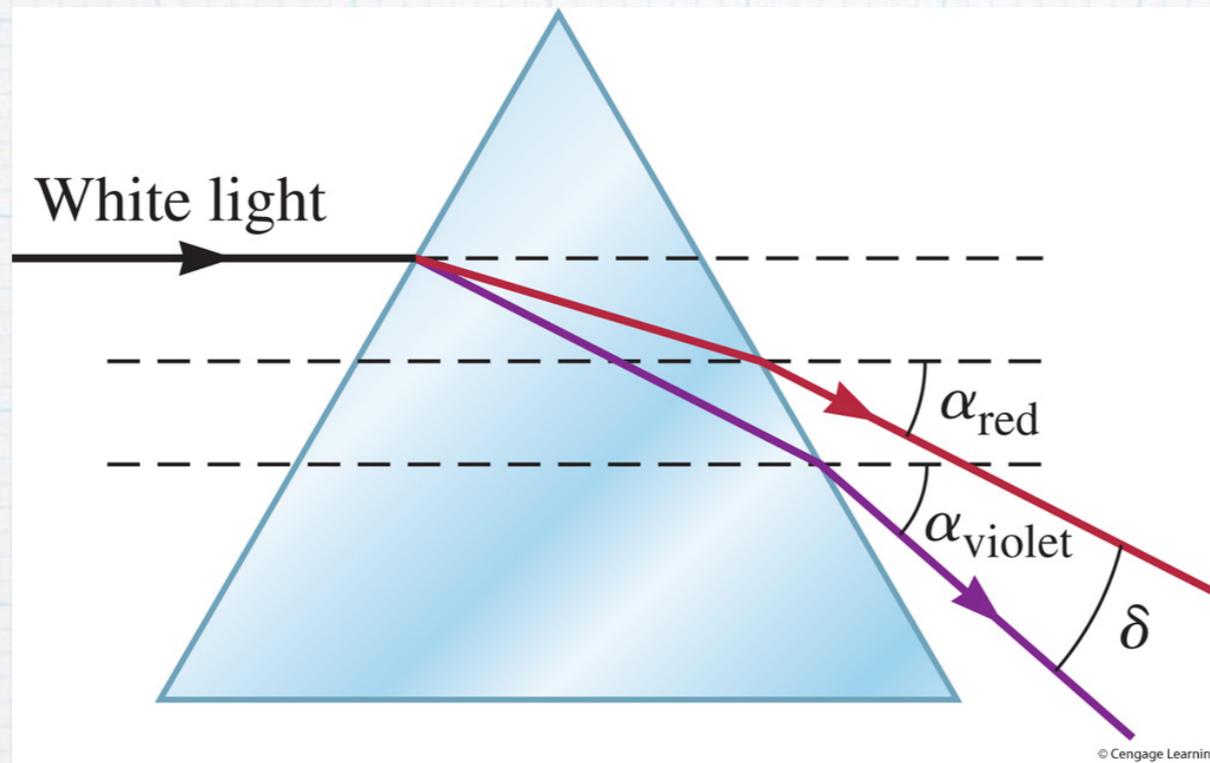

C. Upper rainbow

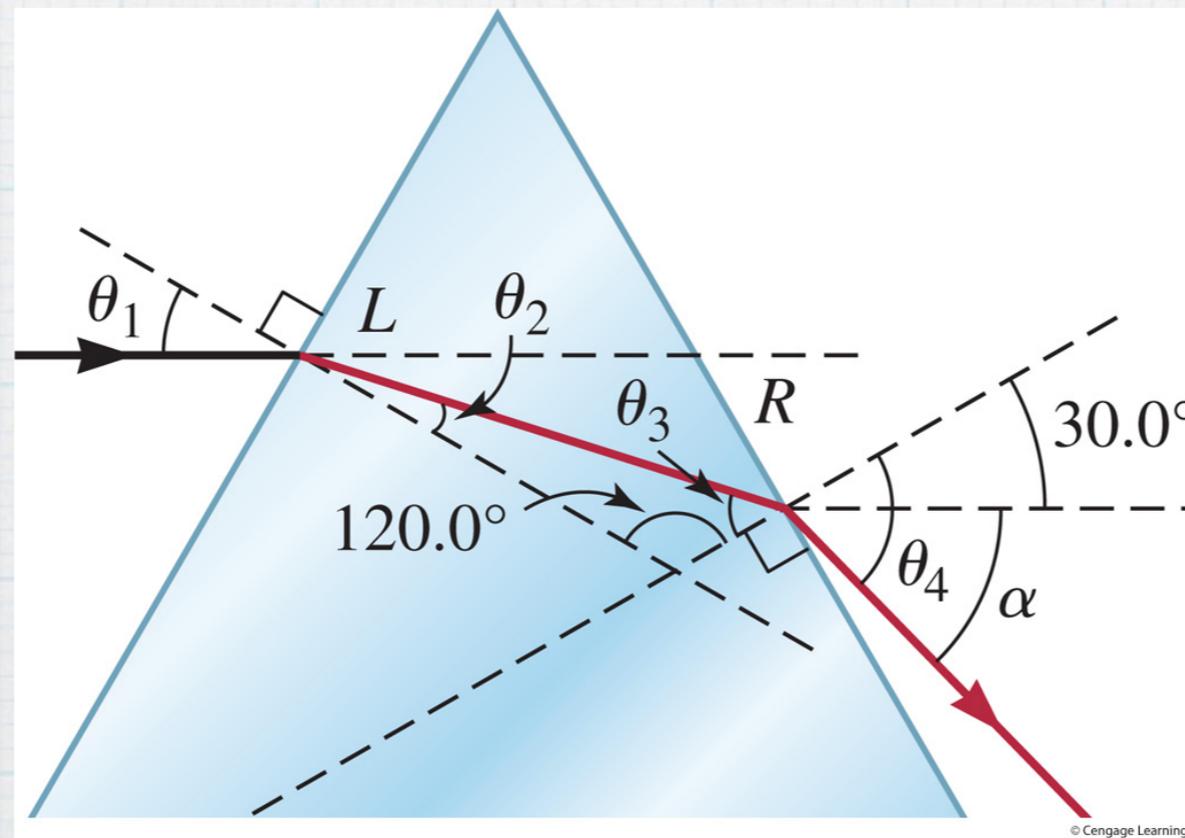

a) Alexey Stiop/Shutterstock.com; b-c) © Cengage Learning

Notice, the ordering of colored is reversed

Example

$\delta?$

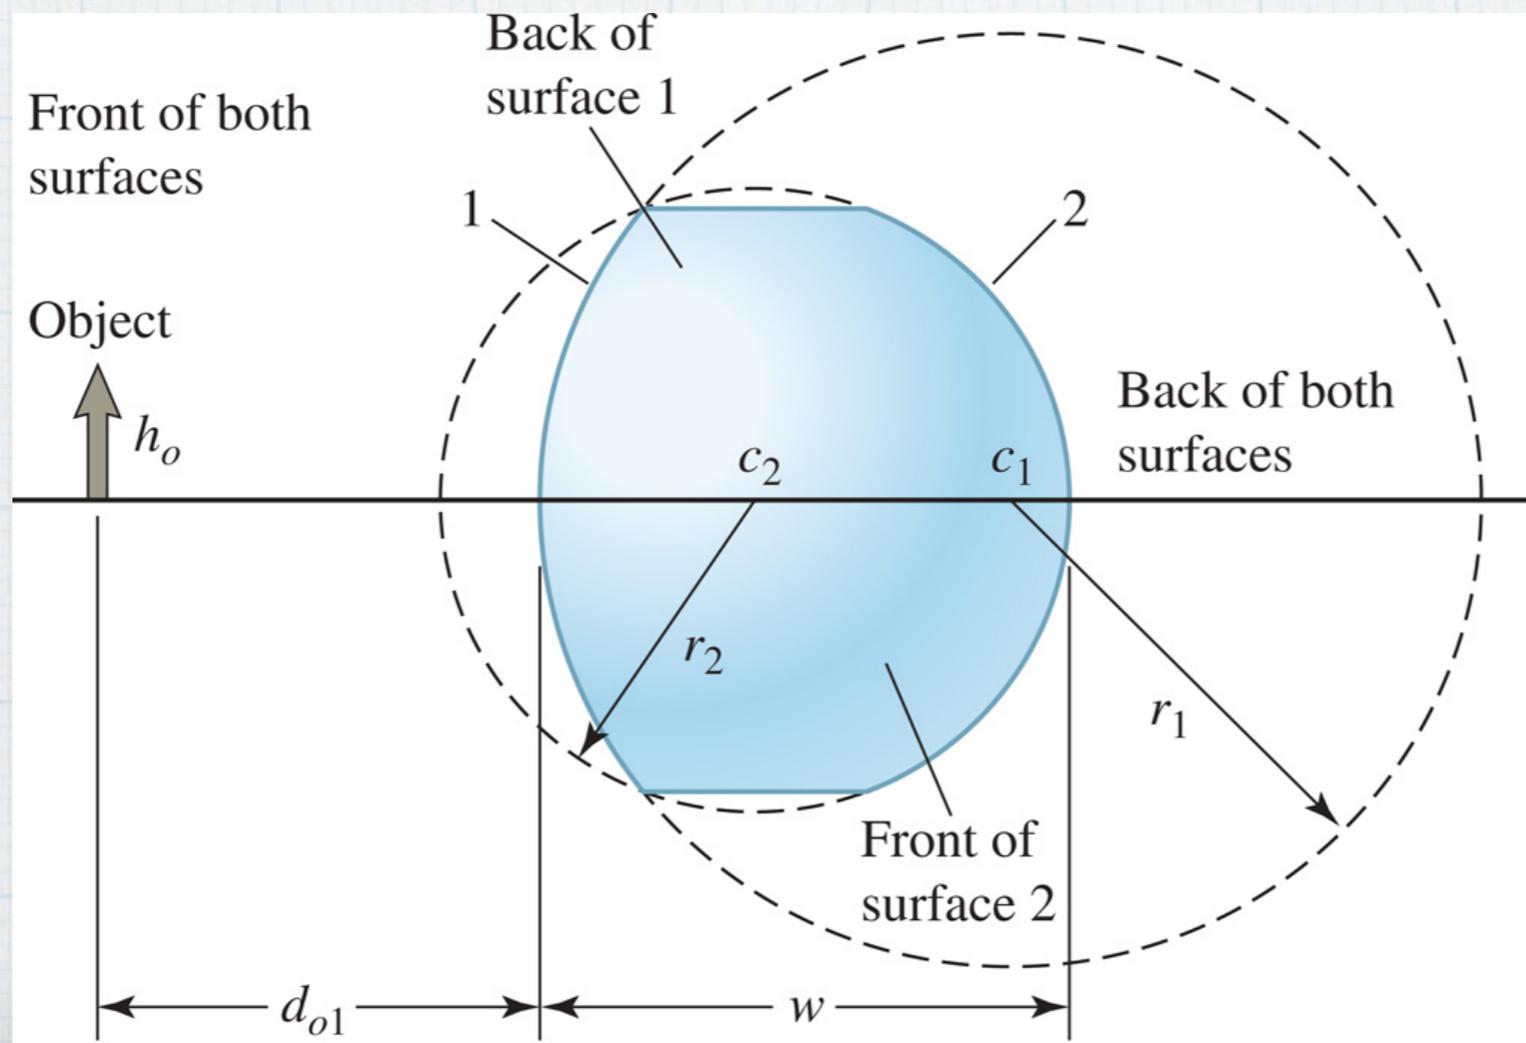

Thin Lenses

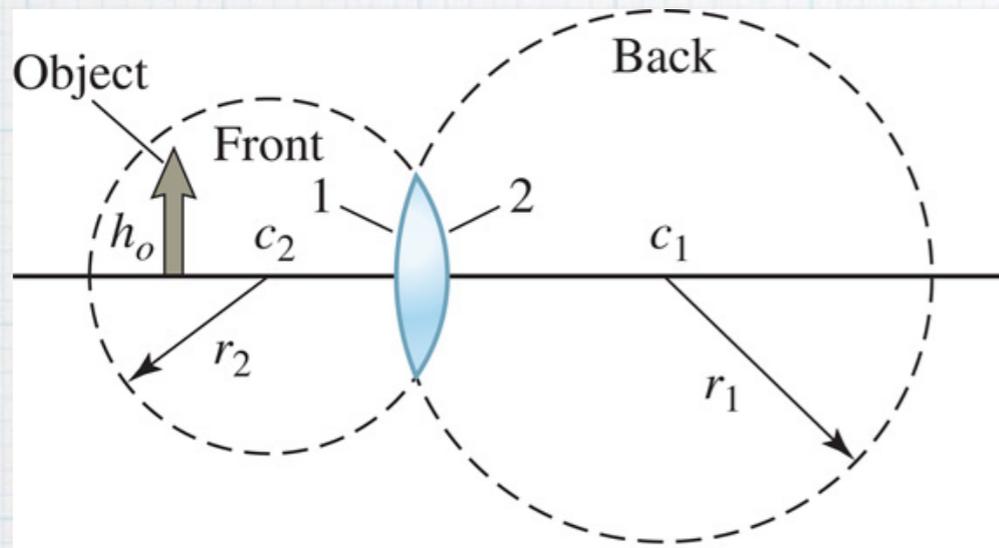

Formed by piecing together 2 pieces of spheres

Lens Maker Equation

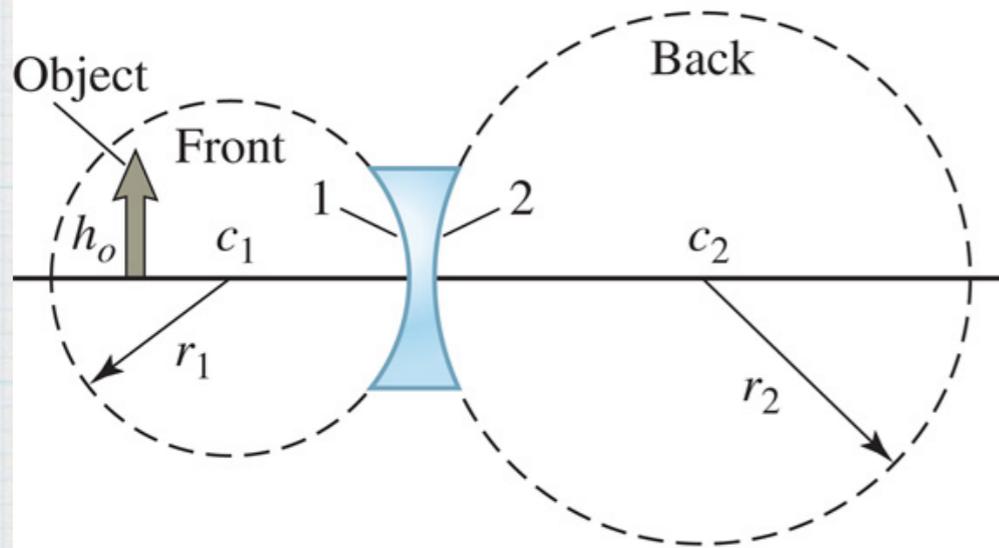

$$\frac{1}{f} = (n - 1) \left[\frac{1}{r_1} - \frac{1}{r_2} \right]$$

Need More to Discuss

TABLE 38.3 Sign conventions for thin spherical lenses.

Quantity	Positive	Negative
1. Image height h_i and magnification M	If image is upright	If image is inverted
2. Object distance d_o	If object is real (in front)	If object is virtual (behind)
3. Image distance d_i	If image is real (behind)	If image is virtual (in front)
4. Radius of curvature r	If surface is convex	If surface is concave
5. Focal length f	If lens is converging	If lens is diverging

What's the sign for the focal lengths of these two?

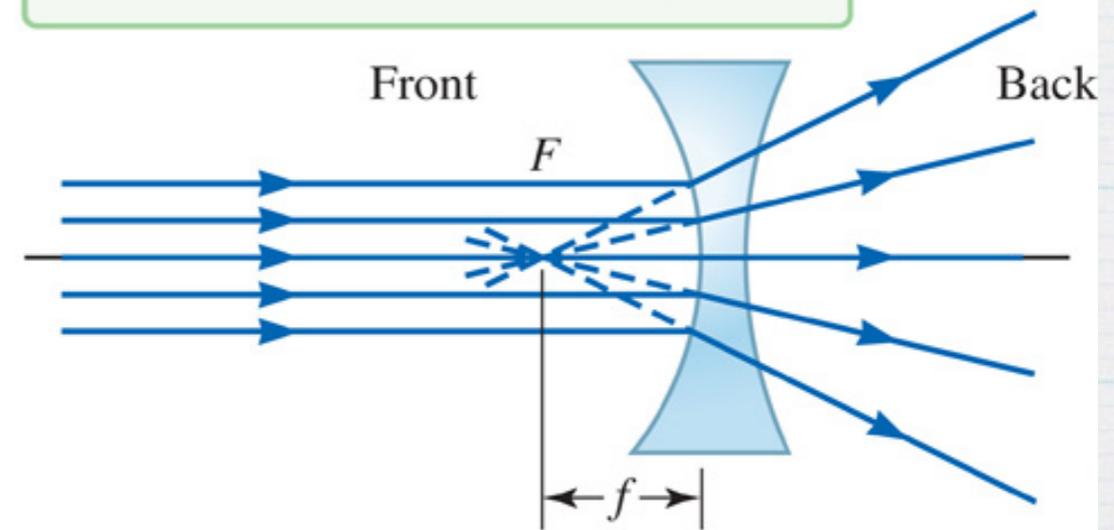

Converging Vs Diverging

Very distant object's rays are parallel.

A. Converging lens

Very distant object's rays are parallel.

B. Diverging lens

© Cengage Learning

Let's design a lens

Generic Image Formation

$$\frac{1}{f} = \frac{1}{d_i} + \frac{1}{d_o}$$

$$M = \frac{h_i}{h_o} = -\frac{d_i}{d_o}$$

TABLE 38.4 Primary rays for thin lenses.

Ray	Converging lens	Diverging lens
<p>Ray 1 passes through the center of the lens. It is not deflected because any ray that passes through the center of the lens goes through two nearly parallel surfaces.</p>		
<p>Ray 2 is parallel to the optical axis. For a converging lens, ray 2's refraction passes through the focal point on the back of the lens. For a diverging lens, ray 2's refraction is bent away from the optical axis. When you extend the refracted ray backward, it passes through the focal point on the front of the lens. Notice that you draw the bend in the ray only where it strikes the vertical line through the middle of the lens.</p>		
<p>For a converging lens, ray 3 passes through the focal point on the front of the lens. For a diverging lens, ray 3 is aimed at the focal point on the back of the lens. For both lenses, the refracted ray is parallel to the optical axis.</p>		

Examples, Math and Rays

Image Behind Focal Point

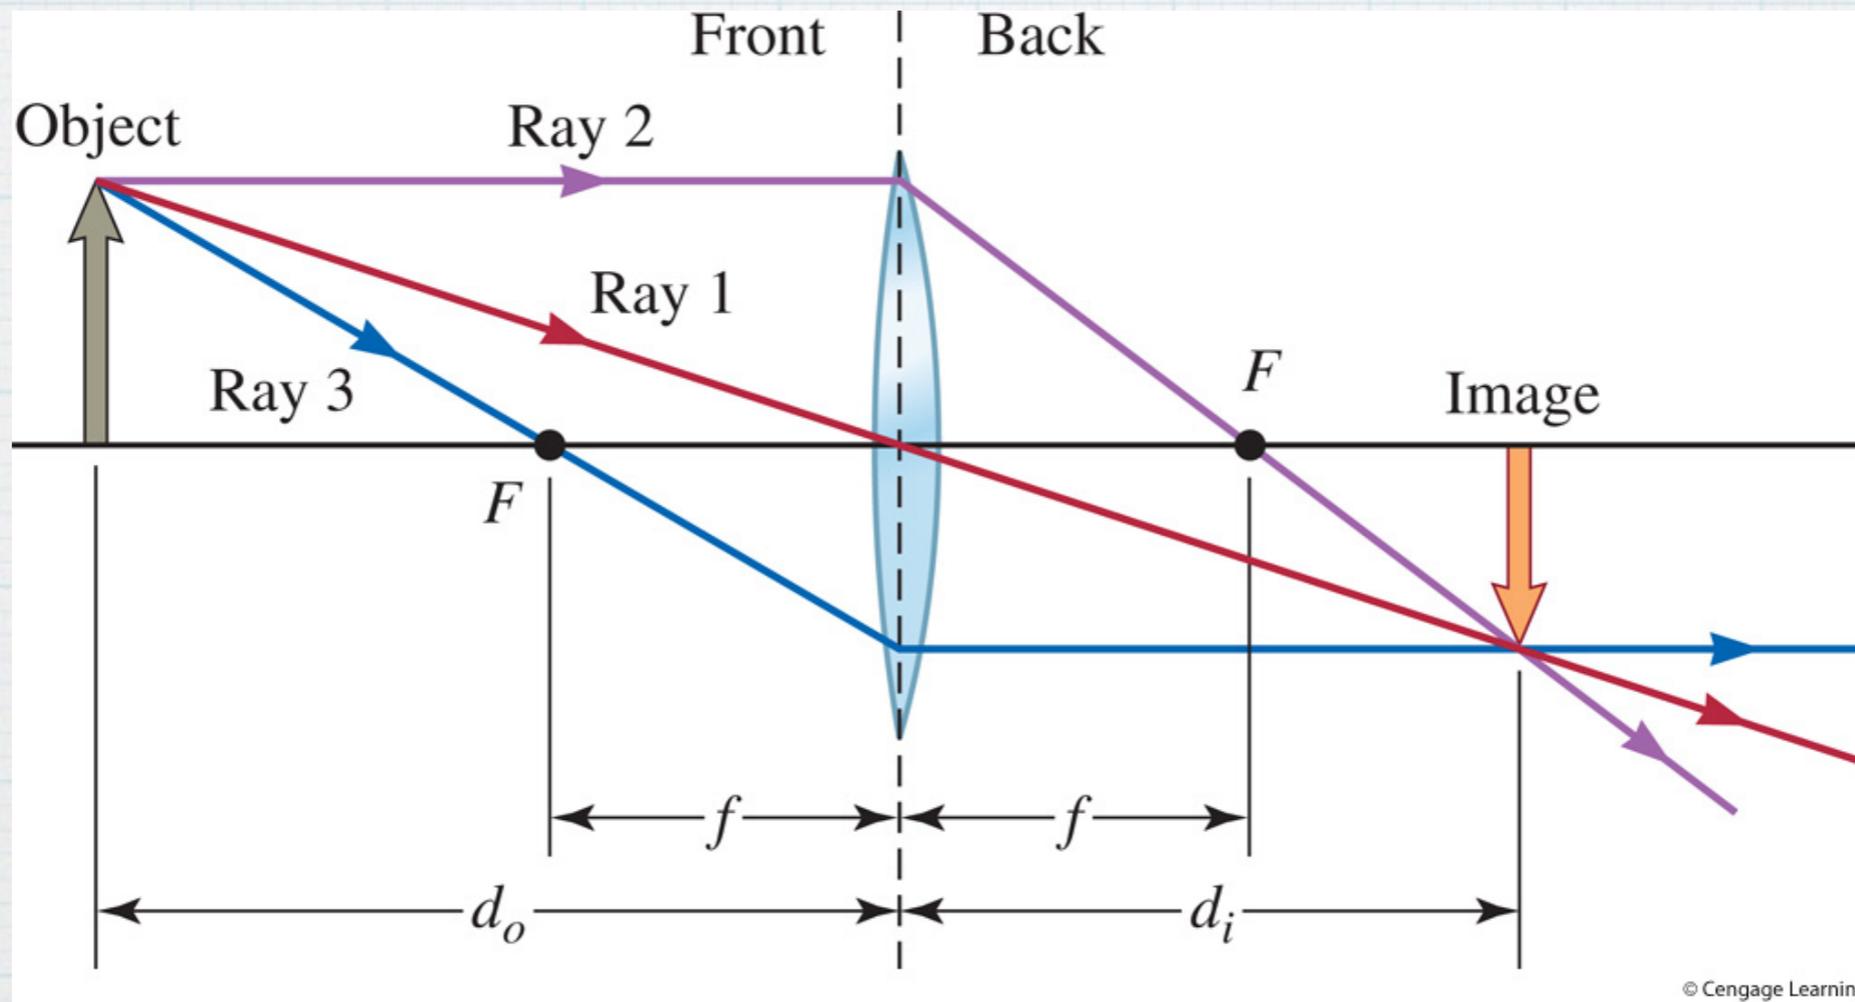

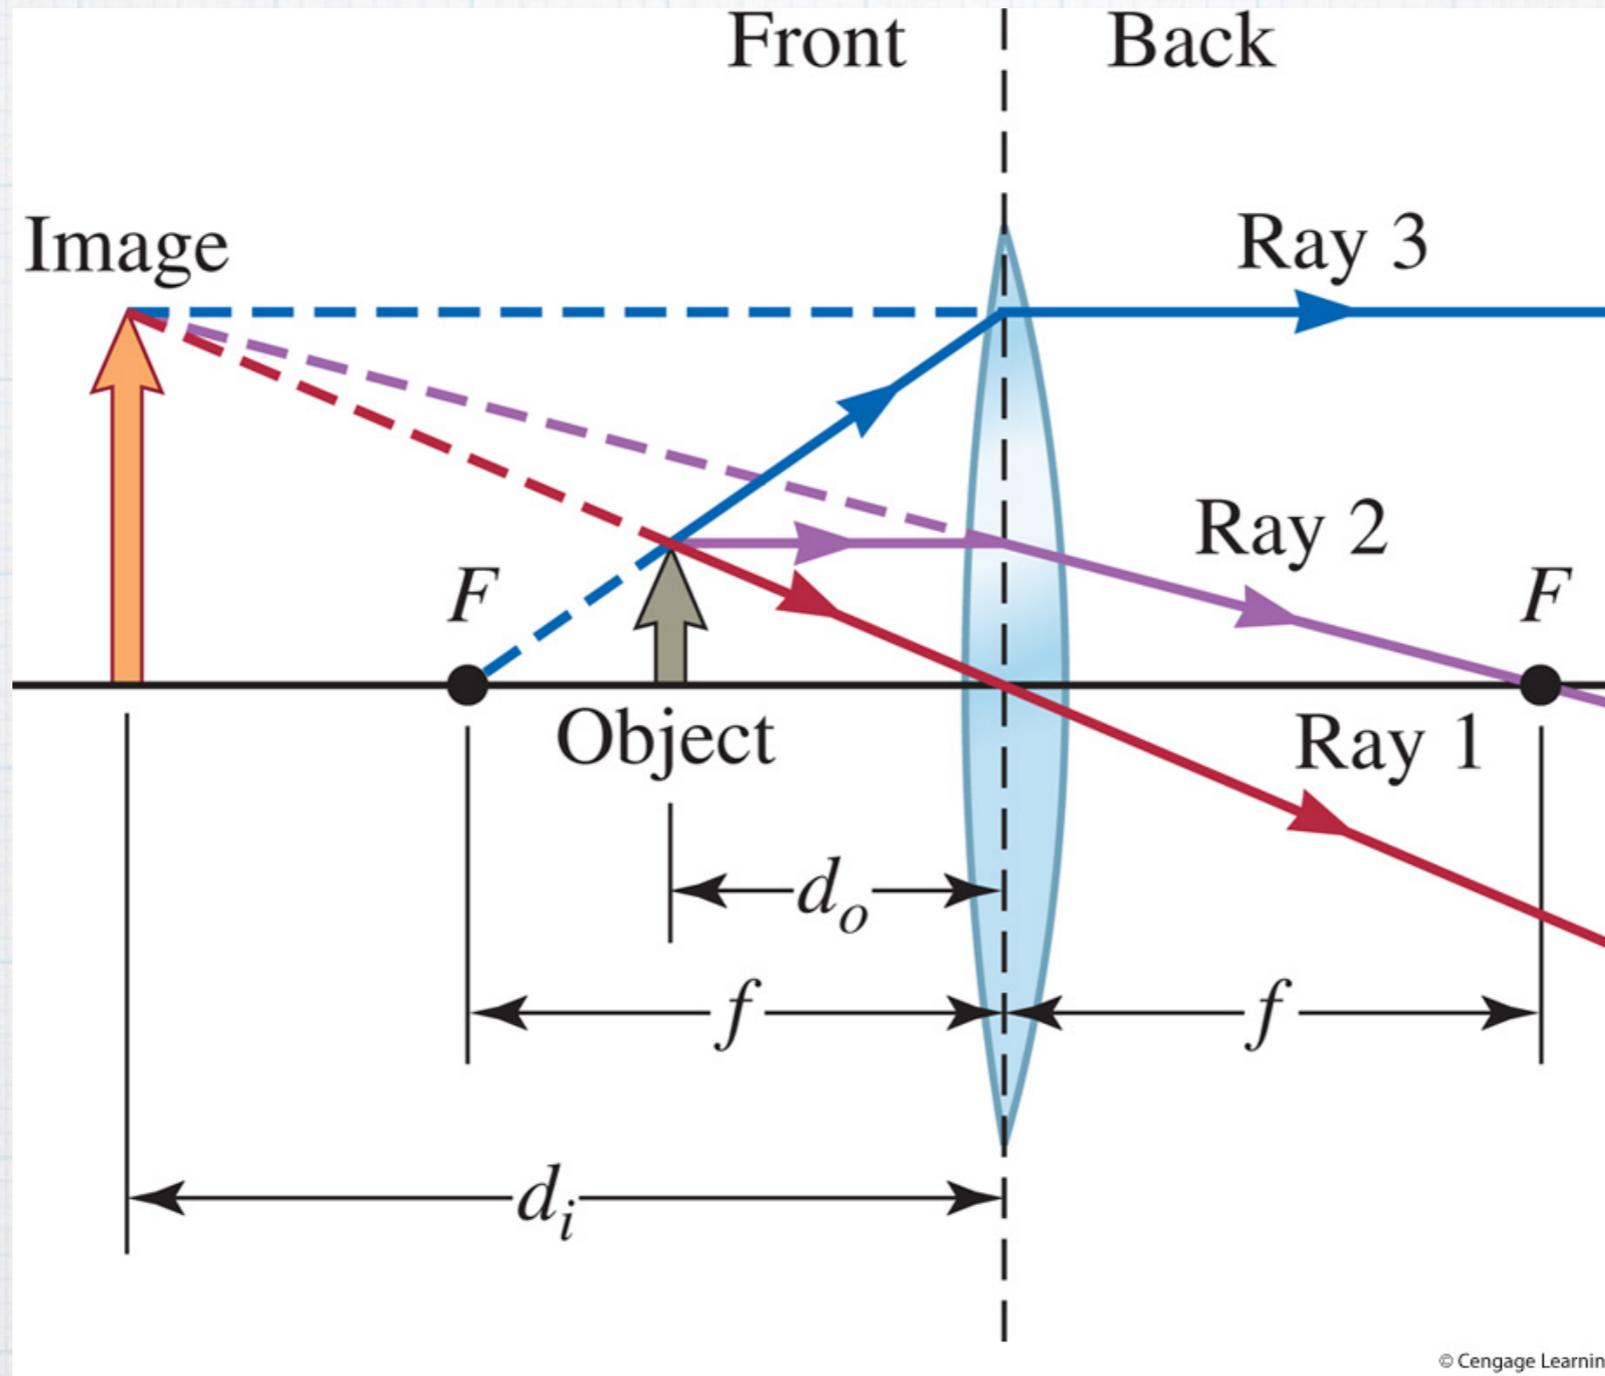

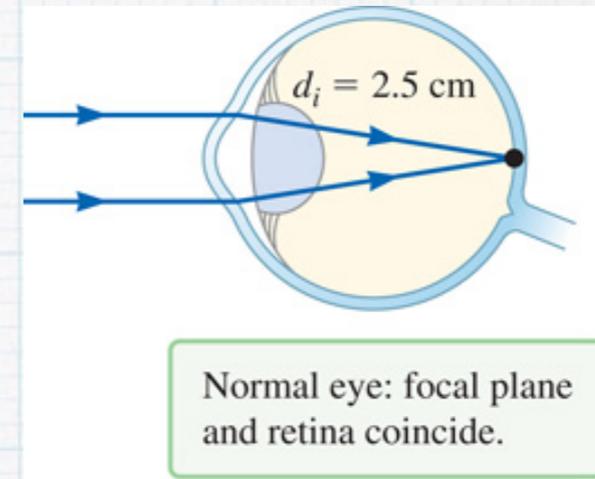

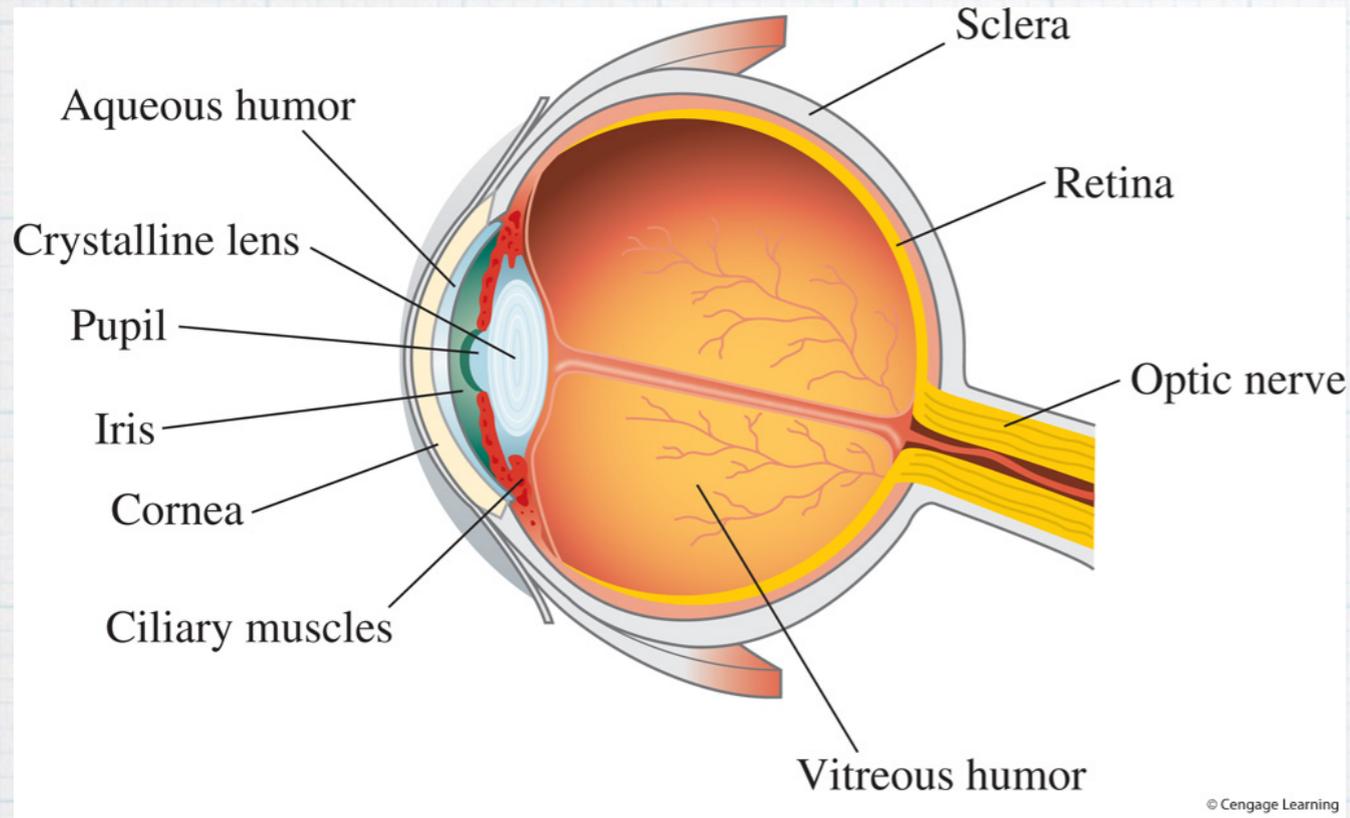

Image in Front of Focal Point

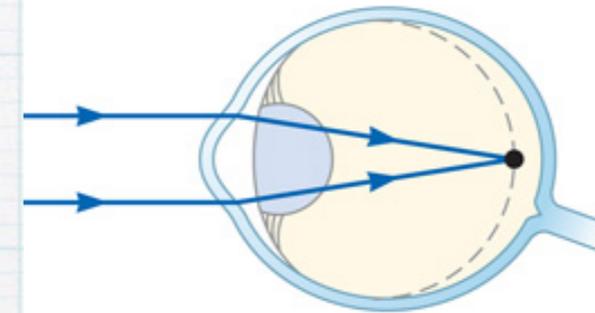

The Eye

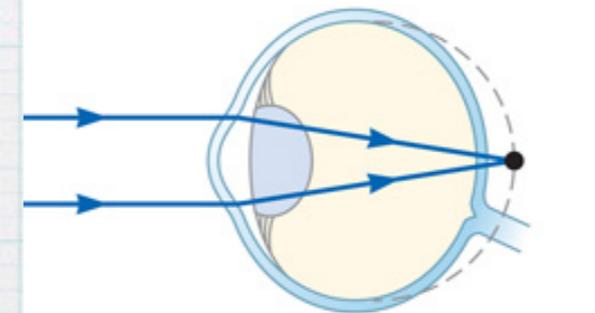

Normal eye: focal plane and retina coincide.

A.

Myopic eye: focal plane is in front of retina.

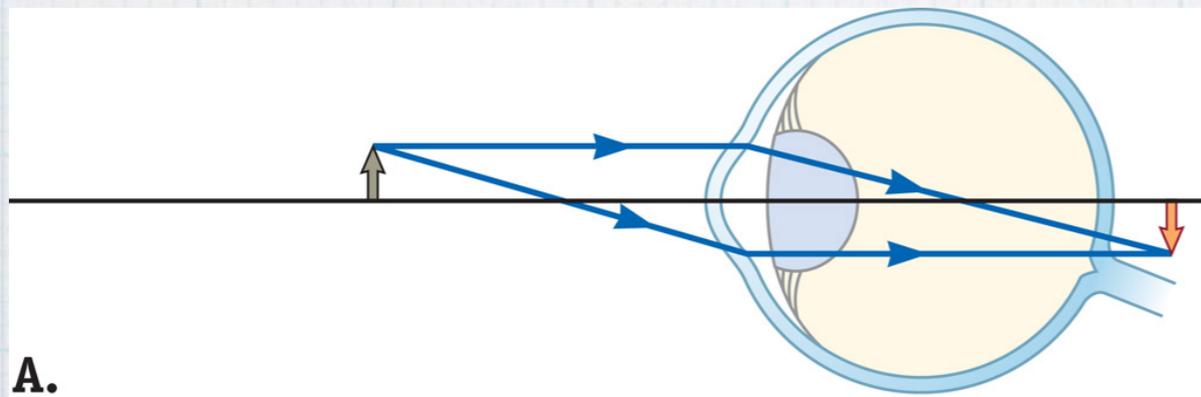

B.

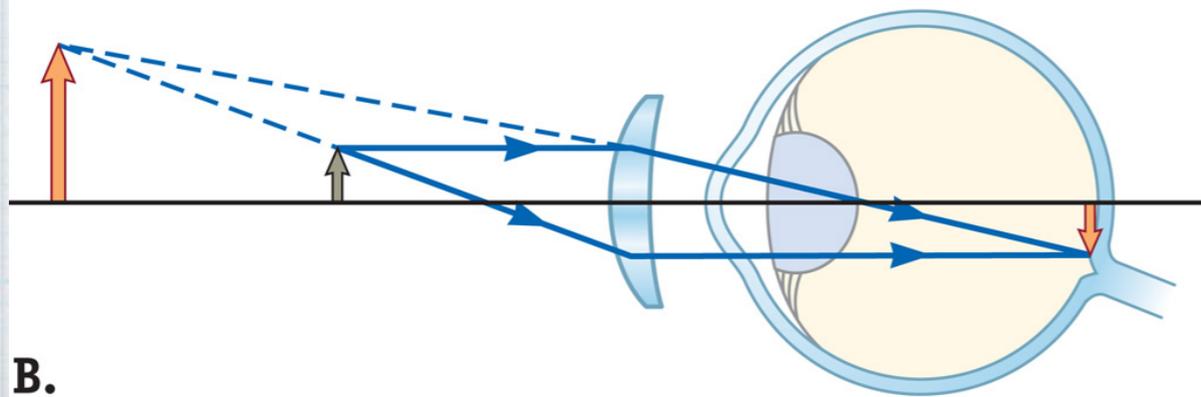

Hyperopic eye: focal plane is behind retina.
