Abstract

Electromyography (EMG) is a technique for evaluating and recording the electrical activity produced by skeletal muscles. The EMG technology can be used to compare muscle activity during different resistance training exercises. **Purpose:** The purpose of this study is to compare EMG activity of the pectoralis major, anterior deltoid, and lateral head of the triceps brachii during a set of flat barbell bench press and flat dumbbell bench press. **Methods:** This study examines five Division II college football linemen lifting a weight that is 40% of their barbell bench press one rep max. EMG leads will be placed on the pectoralis major, anterior deltoid, and lateral triceps brachii. After performing their typical warm-up routine, the subjects will perform one set of six reps on barbell bench press, briefly rest, then one set of six reps on dumbbell bench press that more EMG activity will be observed in all muscles during the dumbbell bench press than in the barbell bench press.

Key Words: EMG, Barbell, Dumbbell, Bench Press, Pectoralis Major, Anterior Deltoid, Triceps Brachii.
